**BUILDING STRONG**®

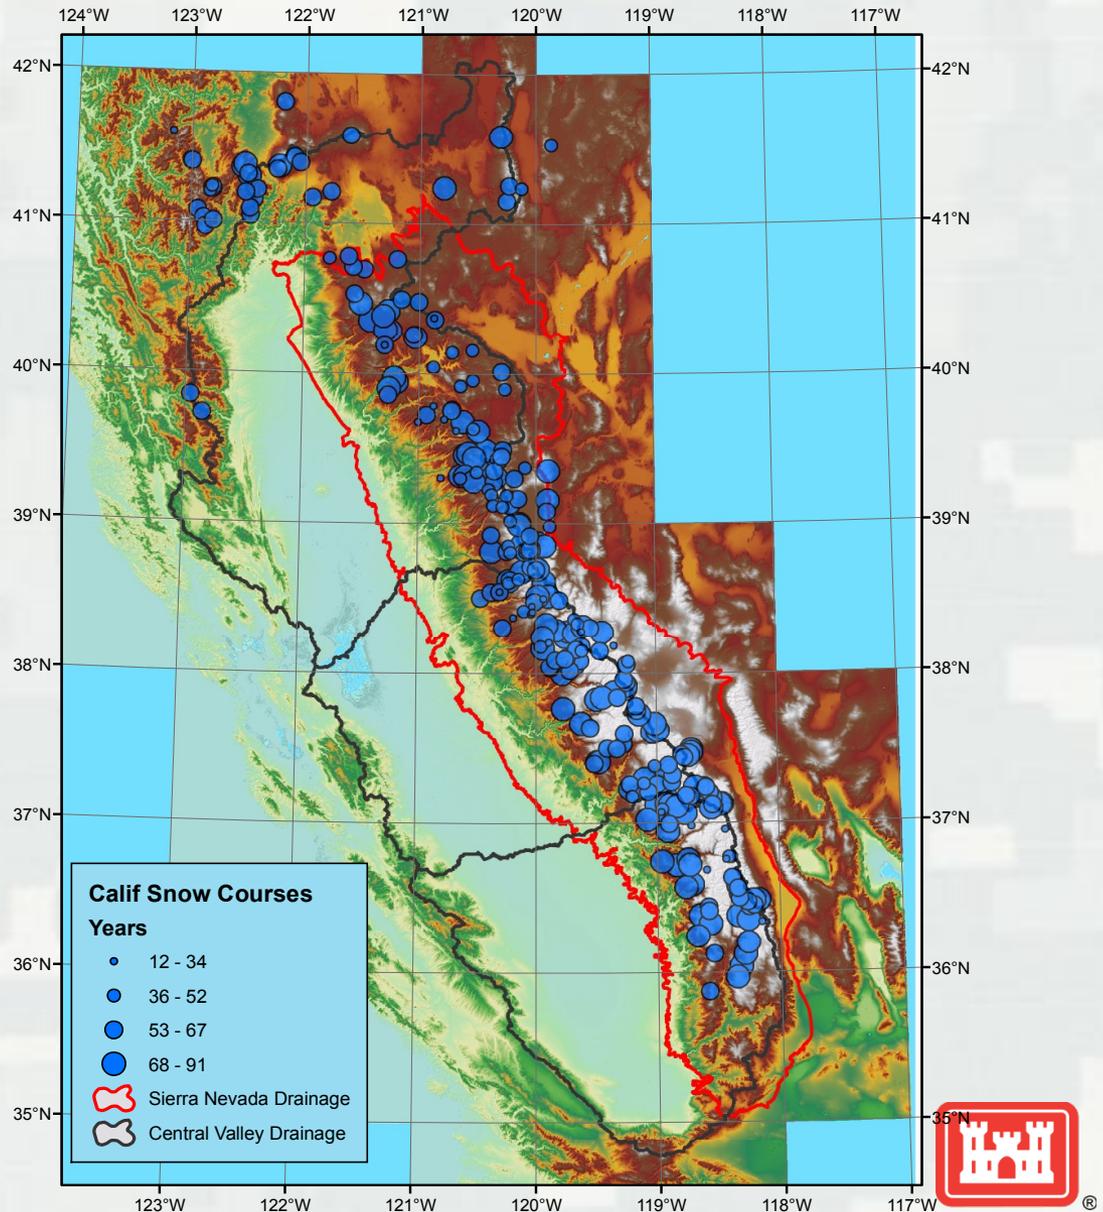

# Does snow present a problem for forecasters?

We don't have a good handle on the distribution of error, but we know about the distribution of concern.

# But we measure and measure!

- 398 snow courses in California
- 213 have “long-term” data:
  - ▶ Measurements in more than 50 years
  - ▶ Starting by 1950
  - ▶ Continuing through 1995

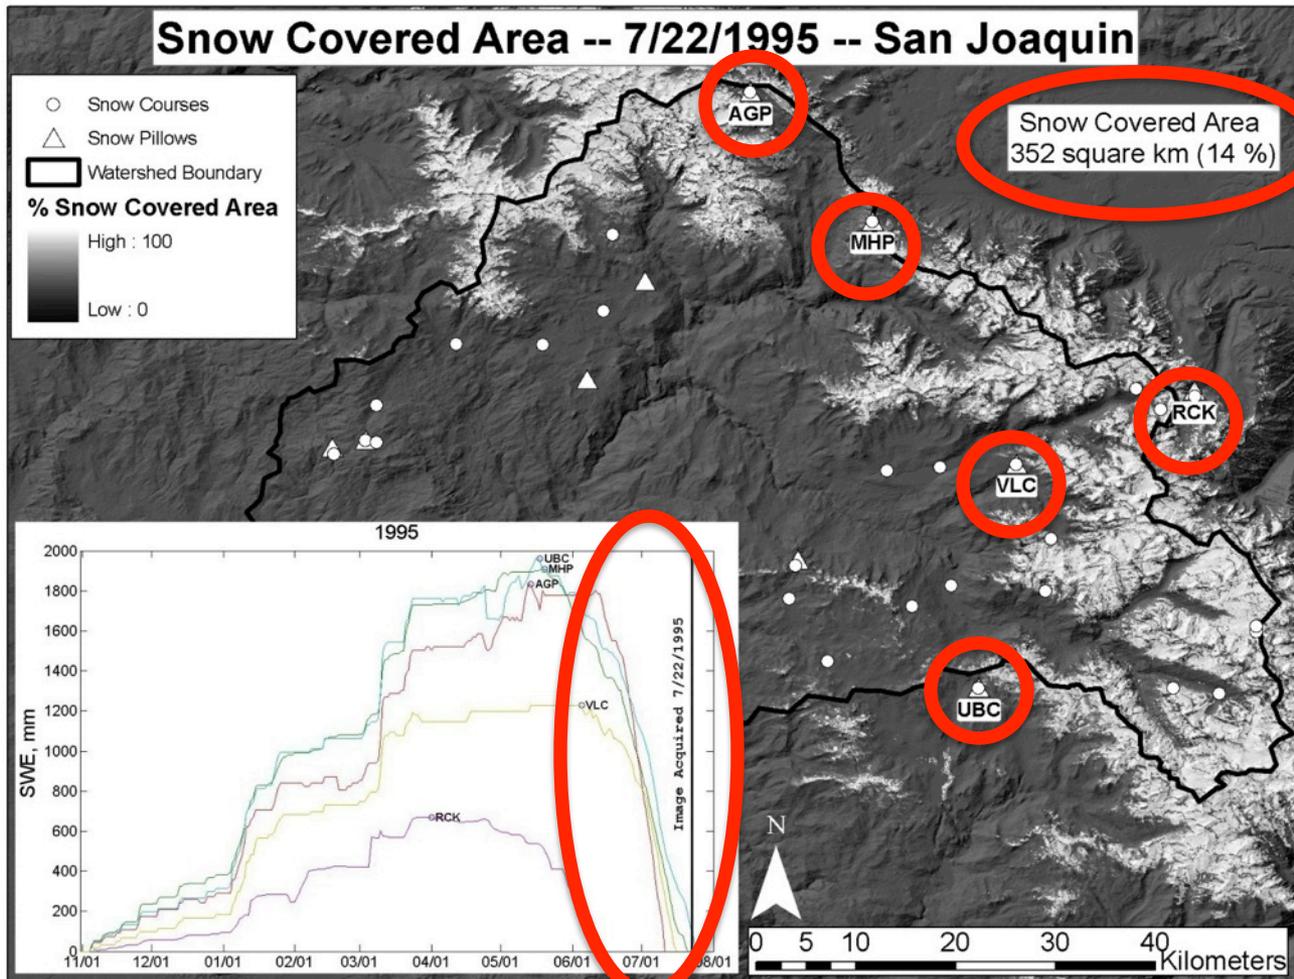

# What more can we do? What don't we know?

- Timing of snow runoff results a combinations from areal depletion and vertical processes (mountains), while volumes seem to wander extremes.
  - ▶ Mapping snow helps us understand what today looks like, spatially.
  - ▶ Measuring snow in critical zones helps us monitor relations between area and volume.
  - ▶ Modeling snow can tell us the trends in estimated volumes.

# Interpolation issues: persistent and high elevation snowpack

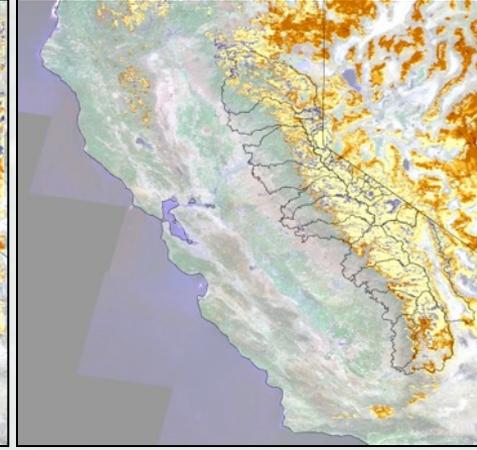

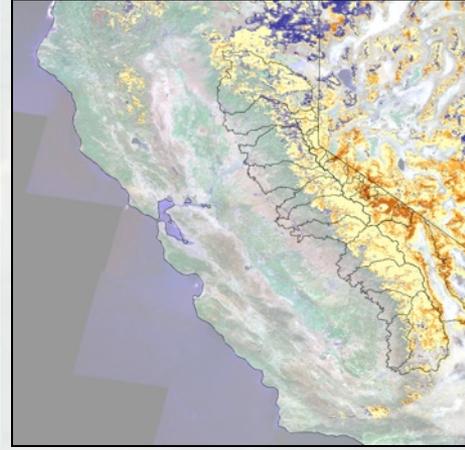

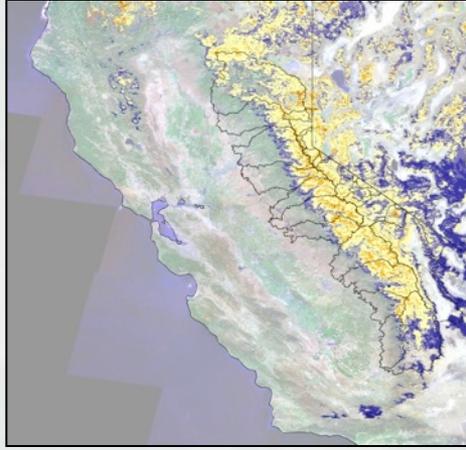

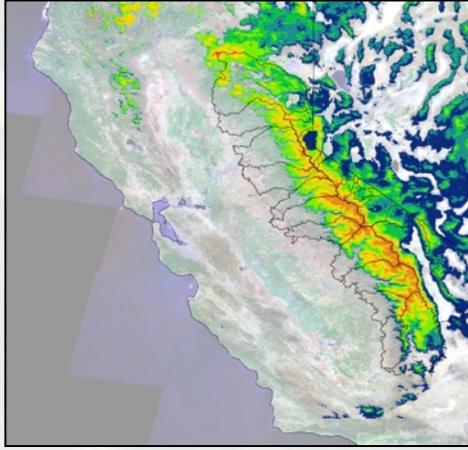

# Snow extent shows us persistence, which exhibits anomalies:

2001 – 2007 Average

2001

2002

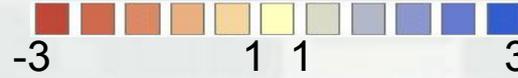

2003

avg. persistence, months

anomaly, months

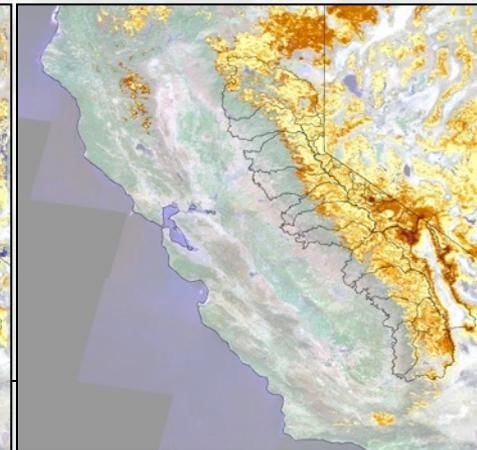

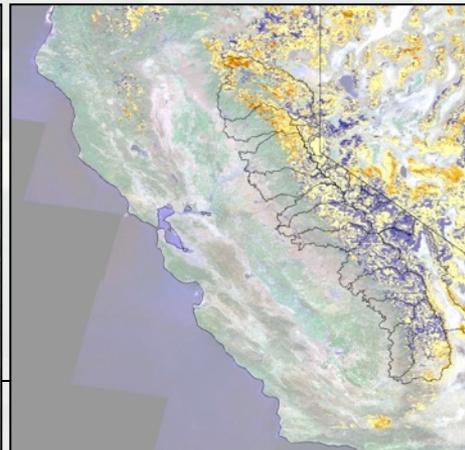

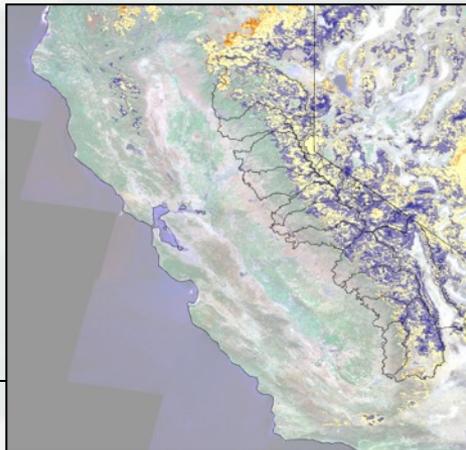

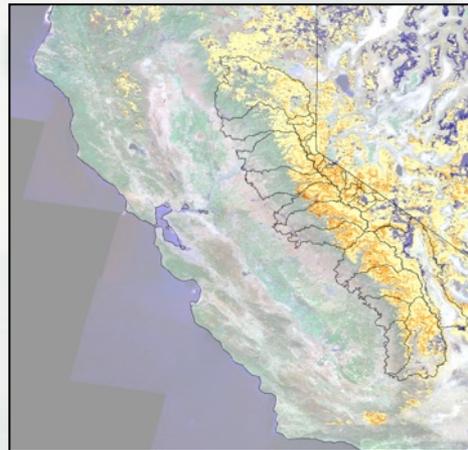

2004

2005

2006

2007

# What if we merge area with observations?

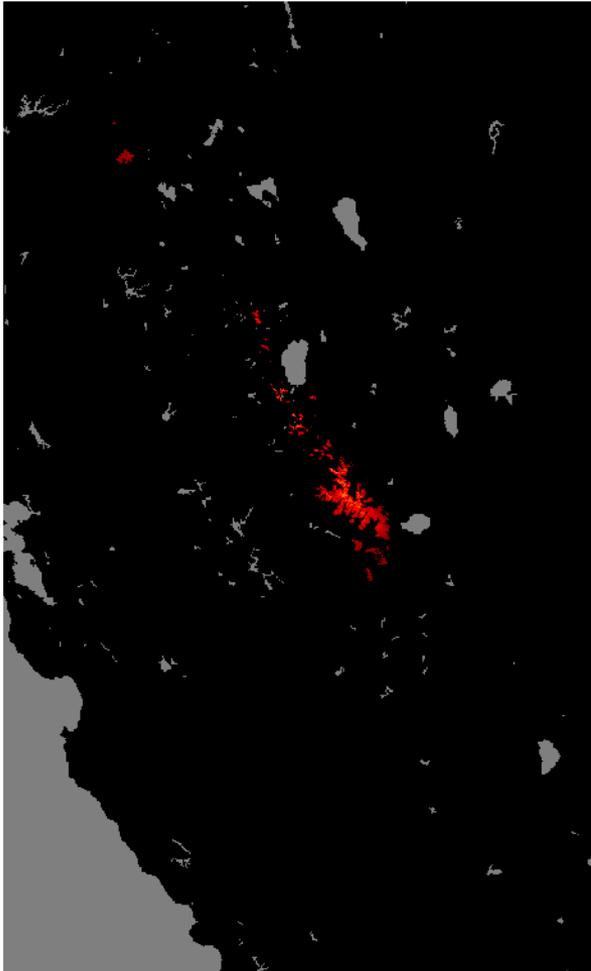

- Spatial interpolation gives us significant errors due to the locations of ground observations; not many where we see the action (low and high).
- “Spatial calorimetry” exploits the persistence maps, merging observations to give us a hind site “reanalysis”.

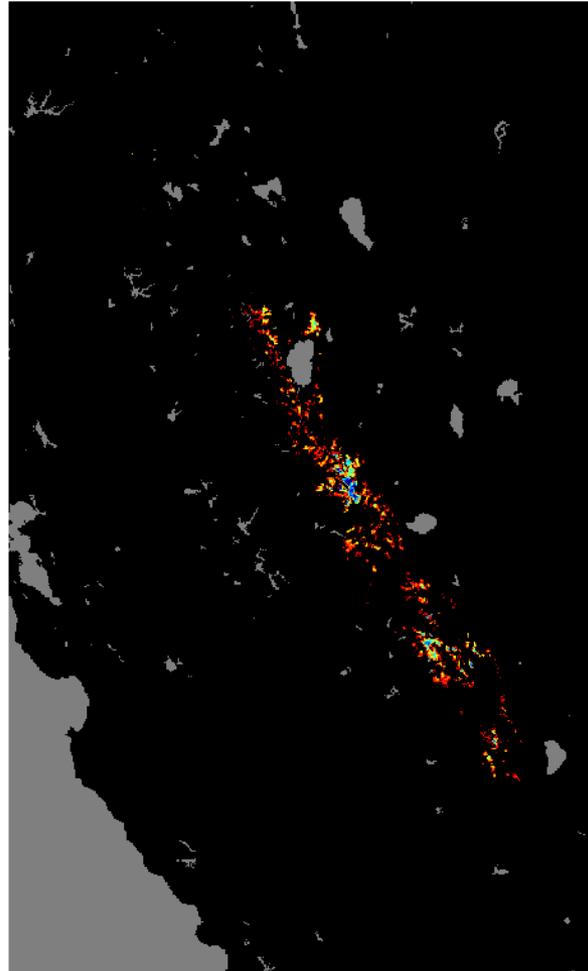

# Lets look how these compare for 2006.

SWE from Interpolation

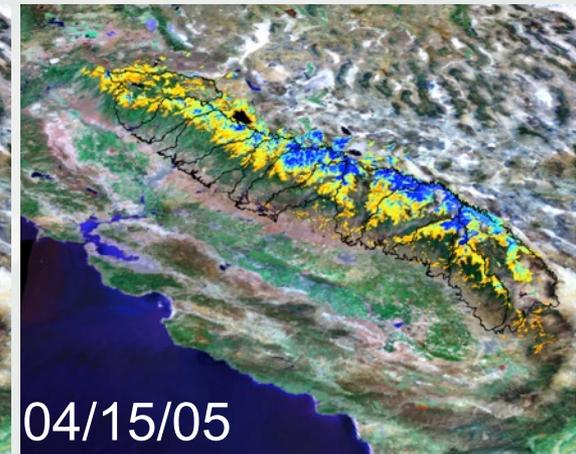

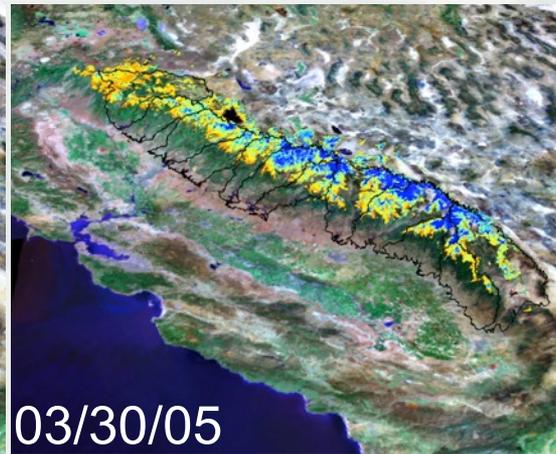

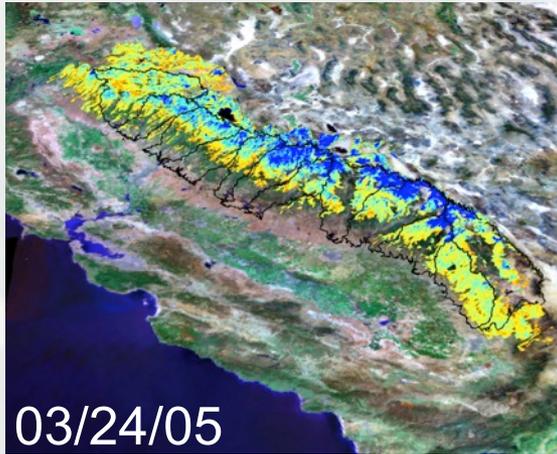

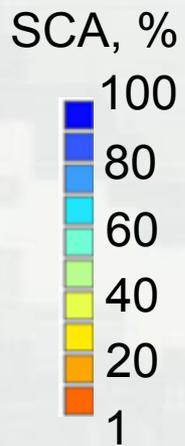

SWE from SNODAS

SWE from Reconstruction

# Range-Scale Snow Cover: MODIS

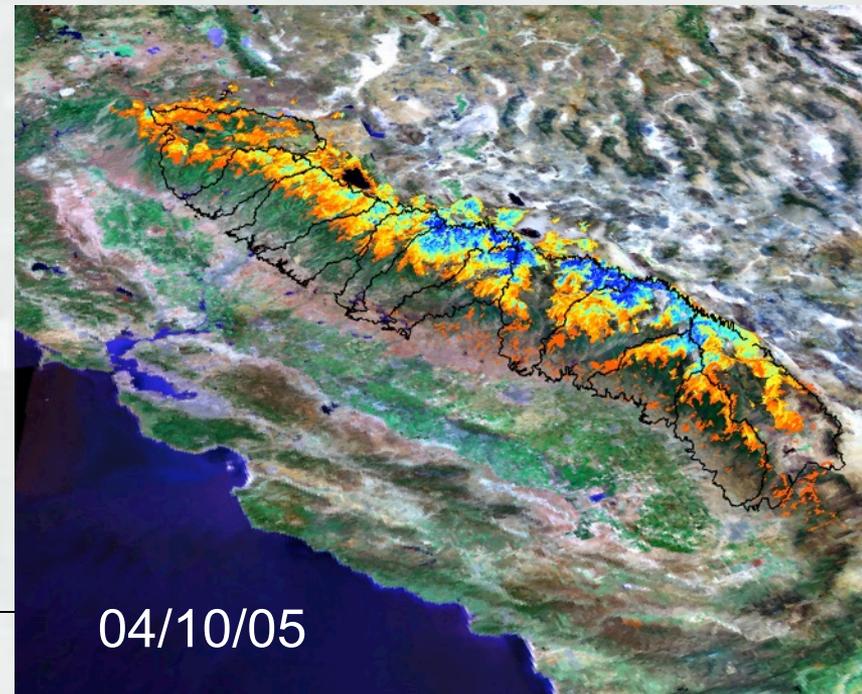

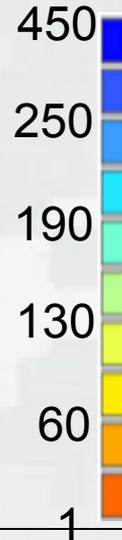

*MODSCAG – Dozier et al., in press*

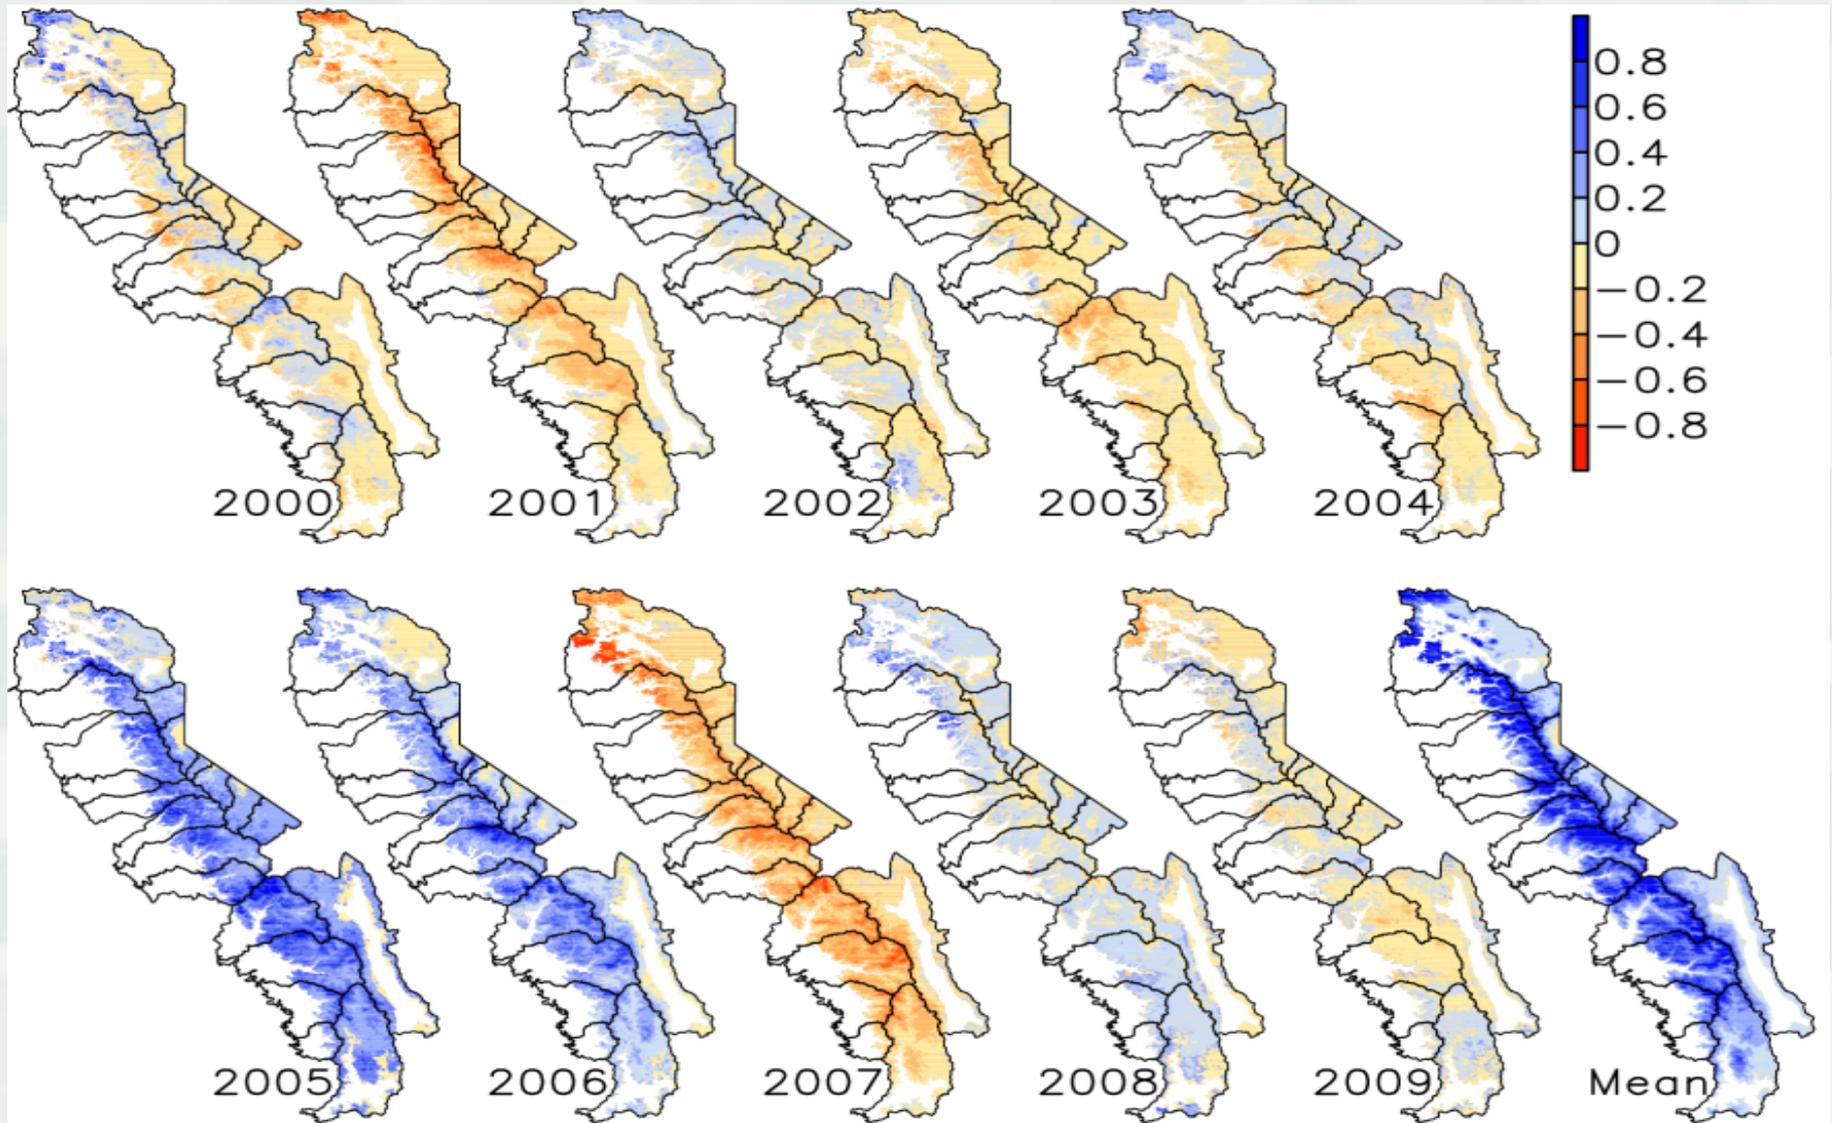

Due to lower initial mass  
snow disappeared  
rapidly in N. Sierra.

Areas with persistent  
snow cover had  
greatest mass.

SWE, cm

# Snow Water Equivalent Anomalies

*Guan, Molotch, Dozier, Painter in prep.*

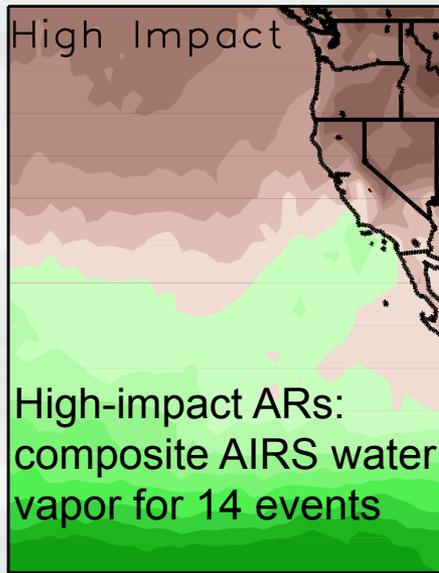

**BUILDING STRONG®**

# So what? Why go to all this effort?

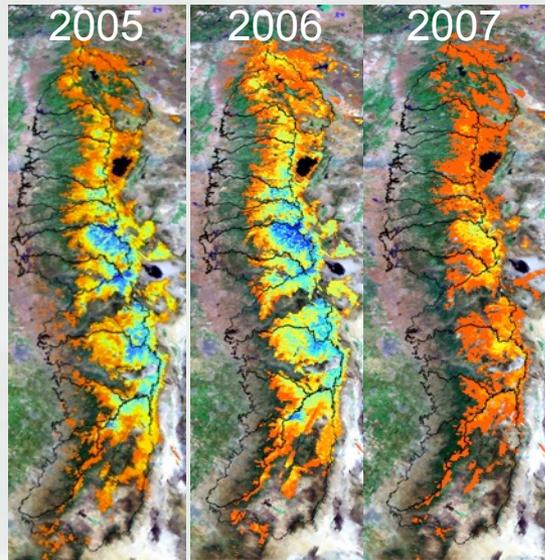

- Scientifically satisfying, since we have a better idea of what we've missed.
  - ▶ *Confirmed what we suspected; large “shallow” low elevation snow and the high country pack explain much.*
- Compliments emerging ideas about precipitation delivery and “integrated investigations”.
- Opens the door to new operational analyses.

# This type of analysis links Atmospheric Rivers and Snow Accumulation in the Sierra Nevada

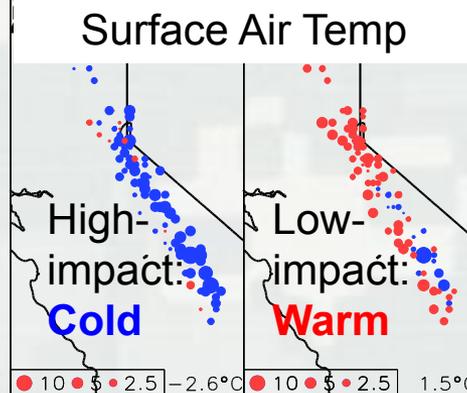

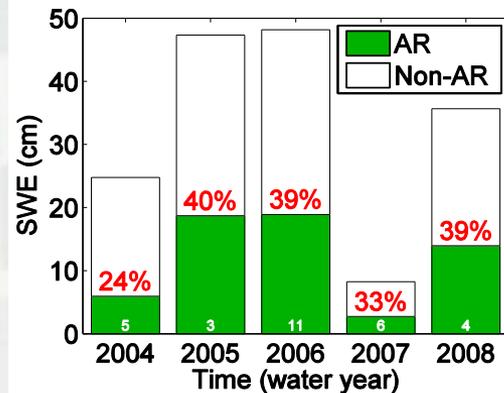

MODIS-model recon SWE

- Atmospheric rivers account for up to ~40% of the total seasonal snow accumulation

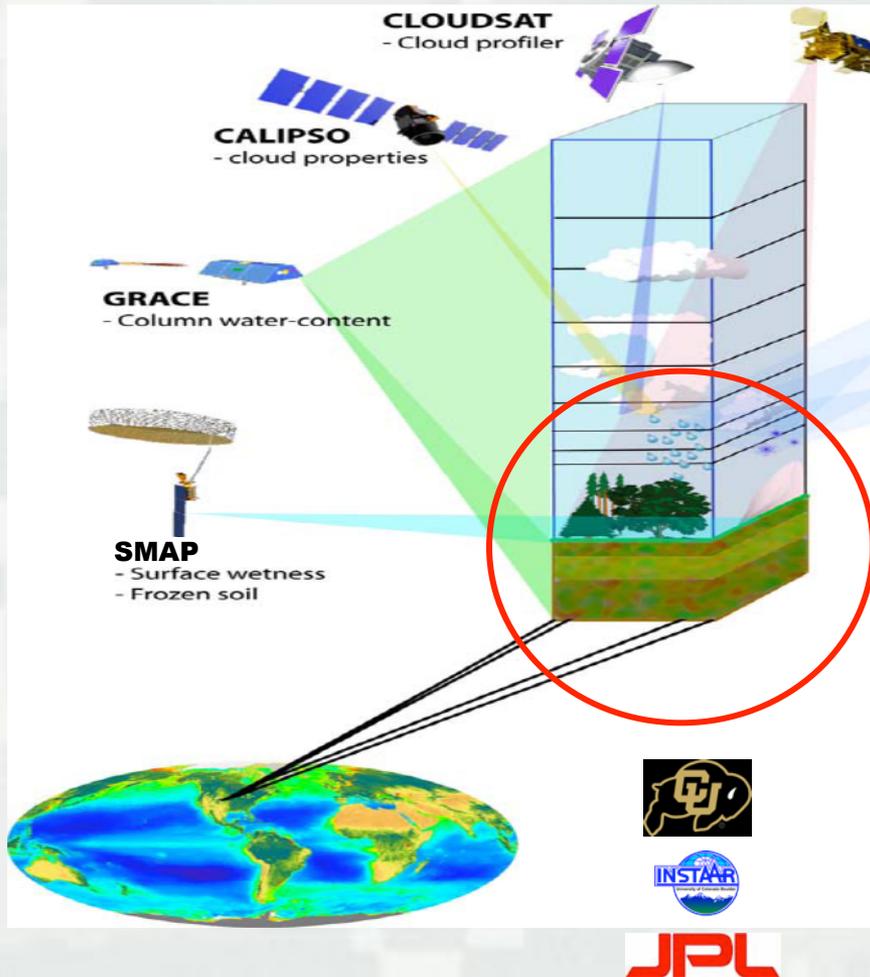

- Surface air temperature partly controls amount of snow accumulation

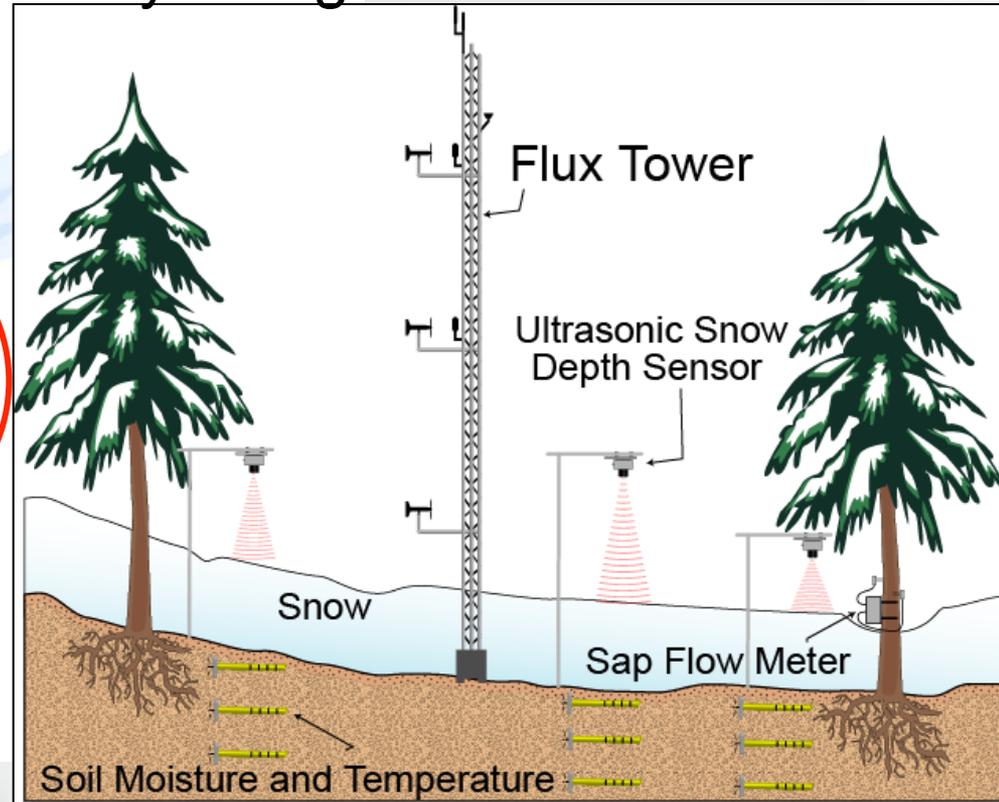

Results illustrate utility of the SWE reconstruction product in understanding hydrologic impacts of extreme precip. Events.

This level of effort broadens our topic spectrum.

## Hydrologic Instrument Cluster

# Can we use the reconstruction to index the past?

- Operational updating and compilation of a SWE library:
  - ▶ We have the tools to exploit large data sets to answer a variety of questions, scientific, operational, and for communicating with the public.
  - ▶ Based on SWE data stacks, we can ask about the most similar priors, and what ran off then.
